Information Systems

MIS Chapter 11 Highlights

3D printing is a process that creates a physical object from a three-dimensional digital mode by laying down many successive layers of material.

Collaborative filtering (CF) is a search for specific information or patterns, using input from multiple business partners and data sources. It identifies groups of people based on common interests and recommends products or services based on what members of the group purchased or did not purchase.

Collaborative planning, forecasting, and replenishment (**CPFR**) is used to coordinate supply chain members through point-of-sale (POS) data sharing and joint planning.

Customer relationship management (CRM) consists of the processes a company uses to track and organize its contacts with customers. It improves services offered to customers and uses customer contact information for targeted marketing.

Customization allows customers to modify the standard offering, such as selecting a different home page to be displayed each time the Web browser is openned.

Electronic data interchange (**EDI**) enables business partners to send and receive information on business transactions.

Enterprise resource planning (ERP) is an integrated system that collects and processes data and manages and coordinates resources, information, and functions throughout an organization.

Knowledge management (KM) draws on concepts of organizational learning, organizational culture, and best practices to convert tacit knowledge into explicit knowledge, create a knowledge-sharing culture in an organization, and eliminate obstacles to sharing knowledge.

Personalization is the process of satisfying customers' needs, building customer relationships, and increasing profits by designing goods and services that meet customers' preferences better. It involves not only customers' requests, but also the interaction between customers and the company.

Supply chain management (SCM) is the process of working with suppliers and other partners in the supply chain to improve procedures for delivering products and services.

e-marketplace is a third-party exchange (**B2B** model) that provides a platform for buyers and sellers to interact with each other and trade more efficiently online.

An **online auction** brings traditional auctions to customers around the globe and makes it possible to sell far more goods and services than at a traditional auction.

A **reverse auction** invites sellers to submit bids for products and services. In other words, there is one buyer and many sellers: a one-to-many relationship. The buyer can choose the seller that offers the service or product at the lowest price.

A **supply chain** is an integrated network consisting of an organization, its suppliers, transportation companies, and brokers used to deliver goods and services to customers.
