Information Systems

MIS Chapter 7 Highlights

MIS Chapter 7 Highlights

The **Internet** is a worldwide collection of millions of computers and networks of all sizes. It is a network of networks.

The **Internet backbone** is a foundation network linked with fiber-optic cables that can support very high bandwidth. It is made up of many interconnected government, academic, commercial, and other high-capacity data routers.

The Web organizes information by using **hypermedia**, meaning documents that include embedded references to audio, text, images, video, or other documents. Composed of billions of hypermedia documents, the Web constitutes a large portion of the Internet.

The embedded references in hypermedia documents are called **hypertext**.

When information is transferred from one network to another, domain names are converted to IP addresses by the **Domain Name System (DNS)** protocol.

You see domain names used in **URLs**.

Hypertext Markup Language (HTML) is the language used to create Web pages. It defines a page's layout and appearance by using tags and attributes. A tag delineates a section of the page such as the header or body; an attribute specifies a value, such as a font color, for a page component.

E-mail is one of the most widely used services on the Internet.

Internet telephony is using the Internet rather than the telephone network to exchange spoken conversations. The protocol used for this capacity is Voice over Internet Protocol (VoIP). To use VoIP, you need a high-speed Internet connection and usually a microphone or headset.

An **intranet** is a network within an organization that uses Internet protocols and technologies.

A **blog** (short for Weblog) is a journal or newsletter that is updated frequently and intended for the general public.

A **podcast** is an electronic audio file such as an MP3 file, that is posted on the Web for users to download to their mobile devices or even their computers.
